Introduction

Mobility datasets quantify population-scale travel in time and space, including trips by distance band. They underpin transport analytics by measuring realised demand, network stress, and environmental exposure, and by supplying empirical baselines when accessibility, pricing, or land use changes alter trip-making. Mobility datasets provide empirical evidence for transport behaviour analysis at national scale (Bureau of Transportation Statistics, 2024).

Distance stratification approximates activity space: short bands capture local circulation and chained errands; medium bands often reflect intra-regional commuting and service access; long bands reflect inter-regional movement. Comparing bands reveals how national mobility distributes across spatial scales instead of relying on a single aggregate intensity.

Regression links aligned daily series across bands, summarising co-movement and providing simple checks alongside R squared and RMSE expressed in natural trip-count units. Contrasting Pandas with Dask addresses scalable analytics: serial code is straightforward to validate; distributed execution may reduce wall-clock time when partitions are large enough to amortise scheduling, serialization, and worker communication.

Four objectives are pursued: (1) summarise weekly national Population Staying at Home and Population Not Staying at Home; (2) quantify distance-stratified intensity and flag dates where medium-distance volumes exceed ten million trips; (3) estimate a linear relationship between Trips 1-25 Miles and Number of Trips 5-10 on merged national dates, reporting RMSE and R squared; (4) benchmark runtime for a replicated workflow under serial Pandas and parallel Dask with ten and twenty workers.

Datasets

Trips_by_Distance.csv contains Level, Date, Week, Population Staying at Home, Population Not Staying at Home, aggregate trips, and binned counts such as Number of Trips 5-10 and Number of Trips 10-25. Trips_Full Data.csv contains national daily distance columns Trips <1 Mile through Trips 500+ Miles plus population and aggregate trip fields used for distance summaries complementary to the distance file.

National filtering keeps a single geography comparable across days. Datetime conversion enables correct ordering, reliable inner merges on calendar dates, and valid weekly aggregation. Duplicate removal avoids inflated means and distorted threshold frequencies. Redundant geographic columns are dropped after retaining National rows to simplify schemas and reduce dtype inference failures in distributed CSV reads.

Methodology

Pandas supplies the baseline: deterministic in-process frames, mature CSV and datetime handling, and plotting integration suitable for reproducible coursework and reference outputs that downstream distributed runs can mirror. Pandas provides efficient tabular data manipulation structures widely used in scientific computing workflows (McKinney, 2010).

Dask partitions frames and executes task graphs on a local cluster to parallelise reads and reductions without altering the substantive analytical steps, enabling a controlled wall-clock comparison on the same logical workflow. Distributed task scheduling enables scalable parallel dataframe processing across cores and clusters (Dask Development Team, 2024).

Weekly means group Trips_by_Distance.csv by Week for Population Staying at Home and Population Not Staying at Home, smoothing daily noise while preserving slower-moving weekly structure visible in bar charts. Distance means average National rows in Trips_Full Data.csv across mile-band columns to summarise typical intensity and to compare category dominance within the national mix.

Thresholding selects dates where Number of Trips 10-25 or Number of Trips 50-100 exceed ten million trips, operationalising an extreme-intensity regime for visual comparison across bands. Regression inner-merges Trips 1-25 Miles from Trips_Full Data.csv with Number of Trips 5-10 from Trips_by_Distance.csv on Date over the overlapping national window to test same-day co-movement between a broad predictor and an adjacent response.

RMSE reports typical absolute error in trip counts; R squared reports variance explained relative to a mean-only benchmark, separating scale-sensitive accuracy from explanatory power for reporting audiences.

Exploratory Data Analysis

Weekly aggregation matches common reporting cadences and improves cross-month comparability. Population staying at home signals reduced out-of-home time and is sensitive to gradual shifts in routine participation. Population not staying at home captures realised travel on the same days and completes the national activity budget implied by the two population fields. Distance comparisons matter because headline totals can conceal concentration in short bands that load local networks and environmental exposures. Short-distance dominance is expected when daily routines remain localised even if occasional long trips are socially salient.

Figures 1ÔÇô3 present weekly home and non-home averages and cross-sectional distance means before thresholding and regression.

Figure 1. Average population staying at home per week

Figure 1 shows weekly mean Population Staying at Home varying gradually without sharp single-week breaks, consistent with slow routine adjustment rather than episodic shocks at this resolution. Late-sample increases, where visible, imply modestly higher average home time and should be read with Figure 2 to infer net mobility change.

Figure 2. Average population not staying at home per week

Figure 2 shows Population Not Staying at Home persistently large and comparatively stable, indicating structurally high national circulation with only modest week-to-week variation around a high mean. Together with Figure 1, the series suggest gradual co-movement within a stable aggregate envelope.

Figure 3. Average trips across distance categories

Figure 3 places the highest means in short bands, led by Trips 1-3 Miles, consistent with local access trips and short segments within wider journeys. This implies commuting systems still generate massive intra-local circulation, so junction reliability, local transit frequency, and active-travel safety remain high-leverage even when longer commutes exist.

Threshold Analysis

Ten million trips marks an extreme national daily count that is simple to communicate across bins. Ten-to-twenty-five-mile movement captures intra-regional circulation between suburbs and centres, distinct from purely local or rare long-haul travel. Frequent medium-band exceedance relative to a longer band suggests repeatable medium-range travel drives many high-volume days. Figure 4 shows temporal clustering of exceedances.

Figure 4. Trips above ten million threshold over time

Regression Model

Trips 1-25 Miles concentrates short-to-medium national volume into one predictor aligned with exploratory distance structure. Number of Trips 5-10 targets an adjacent operational bin beyond the shortest hops, merged on Date for national rows. A positive slope indicates same-day co-movement consistent with shared activity budgets. Coefficient, intercept, RMSE, and R2 are reported in Model Evaluation.

Figure 5 plots observations with the ordinary least squares line. Linear assumptions include an approximately linear conditional mean and limited outlier leverage; violations can mislead even when fit appears strong. Linear regression remains a standard baseline method for interpreting relationships between continuous variables in mobility datasets (James et al., 2021).

Figure 5. Linear regression between distance categories

Model Evaluation

Ordinary least squares on nationally merged daily observations yields the metrics below in original trip-count units.

R2 equals 0.946

RMSE equals 1981454.86

Coefficient equals 0.180985

Intercept equals 49643925.69

R2 equals 0.946 implies the linear predictor explains most day-to-day variation in Number of Trips 5-10 conditional on Trips 1-25 Miles in the merged window, signalling a tight linear association for descriptive reporting. RMSE equals 1981454.86 remains large in absolute terms because national daily counts are enormous, so even proportionally small errors translate into large trip-count deviations. Coefficient and intercept should be read jointly: the slope describes incremental co-movement between bands, while the intercept positions the line. Limitations include strict linearity, omitted weekly or shock structure, and sensitivity to merge coverage across Trips_Full Data.csv and Trips_by_Distance.csv. Model evaluation using RMSE and R squared supports interpretation of predictive accuracy and explanatory strength in statistical learning pipelines (Pedregosa et al., 2011).

Travellers by Distance Band

Figure 6. Distribution of travellers by distance band

Figure 6 shows declining average travellers as distance increases, concentrating routine intensity in short bands and leaving long bands with comparatively small averages. That skew implies infrastructure stress and local air-quality exposures track short-range circulation most closely. Planning therefore prioritises junction capacity, local transit headways, and walking and cycling safety, while longer corridors remain important for connectivity even though they carry a smaller share of average daily mass in these summaries.

Parallel Processing Comparison

Processing mode	Time (seconds)
Serial processing	3.99
Parallel processing with ten workers	9.06
Parallel processing with twenty workers	9.58

The benchmark asks whether partitioned Dask execution accelerates the replicated pipeline relative to serial Pandas on the same logical steps. Sequential runs minimise coordination and keep data movement local to one process. Distributed runs add a scheduler, worker processes, serialization, and partitioned CSV readsÔÇöfixed and variable overhead that can dominate elapsed time when partitions are small or when results must be collected frequently to the client.

Performance scales with size: larger data amortises fixed cluster costs across more bytes and tasks, whereas smaller extracts spend disproportionate time on graph construction and startup. Dask is more compelling for large, repeated partitioned pipelines and when

out-of-core execution avoids memory ceilings. In the recorded coursework run, serial time was 3.99 seconds versus 9.06 seconds with ten workers and 9.58 seconds with twenty workers, illustrating coordination overhead under the tested configuration and moderate data scale. Parallel execution performance depends strongly on dataset size partitioning overhead and scheduler coordination costs (Rocklin, 2015).

Discussion

Short-band dominance structures daily activity around local access and repeated short hops, while medium-distance travel sustains regional connectivity and can spike above the ten-million threshold on busy days. Regression ties Trips 1-25 Miles to Number of Trips 5-10, supporting simple monitoring, nowcast-style checks, and communication of co-movement to non-technical stakeholders. Timing results caution that parallelism is not automatically faster; tool choice should follow data scale, task granularity, and how often results must be consolidated.

Limitations

National aggregation hides spatial heterogeneity and distributional impacts across communities. Seasonality is not isolated, so gradual trends may mix holiday calendars, policy shifts, and structural change. A single linear specification may miss threshold or piecewise behaviour in mobility regimes. The moderate extract size used for timing comparisons limits distributed speedups because coordination costs remain salient relative to compute. Omitted covariatesÔÇöfuel prices, weather, labour-market shocksÔÇörestrict causal interpretation and leave residual variation unexplained. Aggregated national mobility datasets may conceal regional variation that affects interpretation of transport behaviour patterns (Wickham and Grolemund, 2017).

Conclusion

Trips_by_Distance.csv and Trips_Full Data.csv jointly portray weekly home and non-home behaviour, short-band dominance, and medium-distance high-volume days. Regression links Trips 1-25 Miles to Number of Trips 5-10 with R2 equal to 0.946 and RMSE equal to 1981454.86. Serial Pandas outpaced Dask with ten and twenty workers in the recorded benchmark, consistent with coordination overhead. Future work may add geography, seasonality, nonlinear models, larger extracts to retest parallelism, and policy covariates.

AI Use Summary

Tool
ChatGPT

How it was used in this assignment
Used for coursework planning, report structure guidance, coding framework support, wording improvements, and appendix drafting support.

Where it was used
Project planning, document structure, code framework review, figure caption wording, and appendix preparation.

Student statement
AI was used for guidance and structure only. The code was run by the student. The outputs, figures, timings, and model metrics included in the final submission were generated from the student's own execution on the coursework datasets. The final report content was checked and adapted by the student before submission.

Pseudocode

Appendix A.2 Pseudocode

Algorithm: BTS Mobility Analysis Workflow
Input:
- Trips_by_Distance.csv
- Trips_Full Data.csv

Output:
- Weekly home and non-home analysis
- Threshold comparison for trip ranges
- Regression model metrics
- Distance-based plots
- Serial and parallel timing comparison

Begin
1. Load both datasets.
2. Convert Date columns to date format.
3. Filter both datasets to National level only.
4. Remove unused location columns from Trips_by_Distance data.
5. Remove duplicate rows.
6. Group Trips_by_Distance data by Week.
7. Compute the average values for:
   7.1 Population Staying at Home
   7.2 Population Not Staying at Home
8. Plot weekly bar charts for home and non-home populations.
9. From Trips_by_Distance data, select rows where:
   9.1 Number of Trips 10-25 > 10,000,000
   9.2 Number of Trips 50-100 > 10,000,000
10. Count matching dates for each condition.
11. Plot a scatter chart to compare the two threshold groups.
12. Match date ranges between the two datasets.
13. Build a linear regression model using:
    13.1 Predictor: Trips 1-25 Miles
    13.2 Response: Number of Trips 5-10
14. Generate model predictions.
15. Calculate RMSE and R2.
16. Plot the regression scatter graph and fitted line.
17. Compute average travellers by distance category from Trips_Full Data.
18. Plot the distance-trip bar chart.
19. Run the workflow in serial mode.

20. Record the serial execution time.
21. Run the workflow in parallel mode with 10 workers.
22. Record the 10-worker execution time.
23. Run the workflow in parallel mode with 20 workers.
24. Record the 20-worker execution time.
25. Compare all recorded timings in a summary table.
26. Save charts and timing outputs for the report.
End

Flowchart description

Appendix A.1 Flowchart Draft

Start
↓
Load Trips_by_Distance.csv and Trips_Full Data.csv
↓
Convert Date fields
↓
Filter National level rows
↓
Clean and remove irrelevant columns
↓
Question 1:
Compute weekly home and non-home averages
↓
Create weekly bar charts
↓
Question 2:
Filter dates above 10,000,000 for 10-25 and 50-100 trip ranges
↓
Create threshold comparison scatter plot
↓
Question 3:
Align dates and train linear regression model
↓
Evaluate RMSE and R2
↓
Create regression figure
↓
Question 4:
Compute average travellers by distance category

↓
Create distance-trip bar chart
↓
Run serial workflow
↓
Record time
↓
Run parallel workflow with 10 workers
↓
Record time
↓
Run parallel workflow with 20 workers
